#### Abstract

Dimethylplatinum(II) complex $\left[\mathrm{PtMe}_{2}(\mathrm{pbt})\right], 1$, with $\mathrm{pbt}=2-(2-$ pyridyl $)$ benzothiazole ligand, can react with dichloromethane solvent to give the corresponding organoplatinum(IV) complex $\left[\mathrm{Pt}(\mathrm{Cl})\left(\mathrm{CH}_{2} \mathrm{Cl}\right) \mathrm{Me}_{2}(\mathrm{pbt})\right]$. The reaction gives exclusively trans addition product in which Cl and $\mathrm{CH}_{2} \mathrm{Cl}$ are located trans to each other. The suggested mechanism for this oxidative addition reaction was computationally investigated and related species during this process are proposed. DFT calculations show that the reaction proceeds through a transition state with the energy barrier of $97.5 \mathrm{~kJ} \mathrm{~mol}^{-1}$. Attempts to grow crystals of the $\mathrm{Pt}(\mathrm{II})$ complex 1 in $\mathrm{CH}_{2} \mathrm{Cl}_{2} / n$-hexane mixture of solvents forms the dichloro $\mathrm{Pt}(\mathrm{IV})$ complex $\left[\mathrm{PtCl}_{2} \mathrm{Me}_{2}(\mathrm{bpt})\right]$, which its structure is determined by X-ray crystallography.

Keywords: Platinum, Oxidative addition, DFT investigation

## INTRODUCTION

Oxidative addition of small organic molecules to $\mathrm{d}^{8}$ square planar complexes such as $\mathrm{Pd}(\mathrm{II})$ and $\mathrm{Pt}(\mathrm{II})$ complexes is of great interest because this kind of reaction is an elementary reaction, usually first step, in many catalytic processes [1-3]. Among small organic compounds, the reactions of alkyl halides such as MeI and EtI containing C-I bond, with $\mathrm{Pd}(\mathrm{II})$ and $\mathrm{Pt}(\mathrm{II})$ complexes are widely studied [4-11]. In comparison to C-I bond, limited studies on the activation of $\mathrm{C}-\mathrm{Cl}$ bond have been previously reported [12-14]. This is very important because most of common organic solvents such as chloroform and dichloromethane include the $\mathrm{C}-\mathrm{Cl}$ bond. For example, Puddephatt et al. reported [13] the oxidative addition reaction of dichloromethane and chloroform to electron rich dimethylplatinum(II) complexes $\left[\mathrm{PtMe}_{2}\left(\mathrm{~N}^{\wedge} \mathrm{N}\right)\right]$, where $\mathrm{N}^{\wedge} \mathrm{N}$ is dinimine ligands such as $2,2^{\prime}$-bipyridine and 1,10-phenanthroline. The activation of $\mathrm{C}-\mathrm{Cl}$ bonds

[^0]in $\mathrm{CCl}_{4}, \mathrm{CHCl}_{3}, \mathrm{CH}_{2} \mathrm{Cl}_{2}$, and $\mathrm{CH}_{3} \mathrm{Cl}$ by $\left[\left(\kappa^{2}-P, N\right)\right.$ $\left.\mathrm{Ph}_{2} \mathrm{PCH}_{2} \mathrm{CH}_{2} \mathrm{NMe}_{2}\right] \mathrm{PtMe}_{2}$ were also investigated by Schubert et al. [14].

This paper describes the reaction of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solvent with $\left[\mathrm{PtMe}_{2}(\mathrm{pbt})\right]$ including an unsymmetrical supporting ligand pbt (= 2-(2-pyridyl)benzothiazole)), leading to organoplatinum(IV) products, and the structure determination on a dichloroplatinum(IV) complex. Computational study is also used to investigate the suggested mechanism.

## EXPERIMENTAL

## General Remarks

${ }^{1} \mathrm{H}$ NMR spectrum in $\mathrm{CDCl}_{3}$ was recorded using Bruker Avance DPX 250 spectrometer (with TMS as reference). The chemical shifts and coupling constants are in ppm and Hz , respectively. The microanalyses were performed using a ThermoFinigan Flash EA-1112 CHNSO rapid elemental analyzer and melting points were recorded on a Buchi 530 apparatus. Kinetic studies were carried out by using a

Perkin-Elmer Lambda 25 spectrophotometer with temperature control using an EYELA NCB-3100 constanttemperature bath. 2-(2-Pyridyl)benzothiazole (abbreviated as pbt) was purchased from commercial sources and the precursor complex $\left[\mathrm{PtMe}_{2}(\mathrm{pbt})\right]$, 1 [15] was prepared according to literature review.

## Synthesis of $\left[\mathbf{P t C l}\left(\mathbf{C H}_{2} \mathbf{C l}\right) \mathbf{M e}_{2}(\mathbf{p b t})\right], 2$

$\left[\mathrm{PtMe}_{2}(\mathrm{pbt})\right], 1,(0.03 \mathrm{~g}, 0.069 \mathrm{mmol})$ was added to $20 \mathrm{~mL} \mathrm{CH} \mathrm{Cl}_{2} \mathrm{Cl}_{2}$. The reaction mixture was stirred at room temperature for 24 h under dark condition. The solvent was evaporated and the residue was washed with cold diethyl ether and dried under vacuum to give final product 2. Yield: $63 \%$. Anal. Calcd. for $\mathrm{C}_{15} \mathrm{H}_{16} \mathrm{Cl}_{2} \mathrm{~N}_{2} \mathrm{PtS}$ : C 34.5, H 3.1, N 5.4, S 6.1. ## Crystallographic Data

Single crystal X-ray diffraction data for complex 3 were collected on a Bruker KAPPA APEX II diffractometer equipped with an APEX II CCD detector using a TRIUMPH monochromator with a Mo K $\alpha$ X-ray source ( $\lambda=0.71073 \AA$ ). The crystals were mounted on a cryoloop under Paratone-N oil and kept under nitrogen. Absorption correction of the data was carried out using the multiscan method SADABS [16]. Subsequent calculations were carried out using SHELXTL [17]. Structure determination was done using intrinsic methods. Structure solution, refinement, and creation of publication data was performed using SHELXTL. Crystallographic information is reported in Table 1. Crystallographic data for the structural analysis has been deposited with the Cambridge Crystallographic Data Center, No. CCDC 2013003. Copies of this information may be obtained free of charge from: The Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ,

UK. Fax: $+44(1223) 336-033$, Email: deposit@ccdc.cam.ac.uk, or www.ccdc.cam.ac.uk.

## Computational Details

Gaussian 09 was used ${ }^{18}$ to fully optimize the compounds using B3LYP level of DFT. The starting structures were created by the GaussView program and optimized using the CPCM solvation method [19] as implemented in the Gaussian program. The effective core potential of Hay and Wadt with a double- $\xi$ valence basis set (LANL2DZ) was chosen to describe Pt. [20] The $6-31 \mathrm{G}(\mathrm{d})$ basis set was used for all other atoms [21]. Frequency calculations were carried out at the same level of theory to identify whether the calculated stationary point is a minimum (zero imaginary frequency) or a transition-state structure (one imaginary frequency). All data were calculated at standard temperature and pressure ( 298.15 K and 1.0 atm .). We have also checked that imaginary frequencies exhibit the expected motion.

## RESULTS AND DISCUSSION

Compounds reported in this work (2-3) are synthesized as outlined in Scheme 1. As reported, Puddephatt and co-workers [13] have investigated the oxidative addition reactions of some platinum(II) complexes with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and $\mathrm{CHCl}_{3}$. For example, $\mathrm{Pt}(\mathrm{II})$ complexes such as $\left[\mathrm{PtMe}_{2}\left(\mathrm{~N}^{\wedge} \mathrm{N}\right)\right]\left(\mathrm{N}^{\wedge} \mathrm{N}=2,2^{\prime}\right.$-bipyridine or 1,10-phenanthroline) were reacted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and $\mathrm{CHCl}_{3}$, to give the $\mathrm{Pt}(\mathrm{IV})$ products, $\left[\mathrm{Pt}(\mathrm{Cl})\left(\mathrm{CH}_{2} \mathrm{Cl}\right) \mathrm{Me}_{2}\left(\mathrm{~N}^{\wedge} \mathrm{N}\right)\right]$ and $\left[\mathrm{Pt}(\mathrm{Cl})\left(\mathrm{CHCl}_{2}\right) \mathrm{Me}_{2}\left(\mathrm{~N}^{\wedge} \mathrm{N}\right)\right]$, respectively. In the present work, the oxidative addition of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, as both reagent and solvent, to the $\mathrm{Pt}(\mathrm{II})$ complex $\left[\mathrm{PtMe}_{2}(\mathrm{pbt})\right]$, 1 , cleanly gave pale yellow solutions at room temperature under dark condition from which the trans addition platinum(IV) product $\left[\mathrm{PtCl}\left(\mathrm{CH}_{2} \mathrm{Cl}\right) \mathrm{Me}_{2}(\mathrm{pbt})\right]$, 2, was obtained in $63 \%$ yield. Complex 2 is a yellowish solid that is characterized by elemental analysis and NMR spectroscopy. In the ${ }^{1} \mathrm{H}$ NMR spectrum of the complex 2 (Fig. 1), the two singlet resonances at $\delta=1.60$ and 1.80 ppm were assigned to the two different methyl ligands being trans to the two different N ligating atoms of the pbt chelating ligand with ${ }^{2} J_{\mathrm{PtH}}=72.5$ and 75.0 Hz , respectively. These ${ }^{2} J_{\mathrm{PHH}}$ values are smaller than corresponding values reported for the methyl
$\mathrm{Csp}^{3}-\mathrm{Cl}$ bond Activation Promoted by a Methylplatinum(II) Complex/Inorg. Chem. Res., Vol. 4, No. 2, 132-139, December 2020.

Scheme 1. Reactions studied in the present work
groups of complex $1\left({ }^{2} J_{\mathrm{PtH}}=88.8\right.$ and 89.6, respectively) [15], confirming the oxidation of $\mathrm{Pt}(\mathrm{II})$ center to $\mathrm{Pt}(\mathrm{IV})$ by dichloromethane. Due to the different chemical environments, the methylene protons of the $\mathrm{CH}_{2} \mathrm{Cl}$ group are diastereotopic and appeared as two doublets at $\delta=3.62$
$\left({ }^{2} J_{\mathrm{HH}}=7.5 \mathrm{~Hz},{ }^{2} J_{\mathrm{PHH}}=45.0 \mathrm{~Hz}\right)$ and $\delta=3.83\left({ }^{2} J_{\mathrm{HH}}=7.5 \mathrm{~Hz}\right.$, ${ }^{2} J_{\text {PtH }}=60.0 \mathrm{~Hz}$ ). The doublet signal at 8.92 ppm showing a ${ }^{3} J_{\mathrm{PtH}}$ coupling of 11.4 (with ${ }^{3} J_{\mathrm{HH}}=5.0$ ) is attributed to the proton of CH group adjacent to nitrogen ligating atom of the pyridyl group of the pbt ligand.

Fig. 1. (A) ${ }^{1} \mathrm{H}$ NMR spectrum of complex 2 in $\mathrm{CDCl}_{3}$. Peak assignments and platinum satellites are shown for the complex.

Scheme 2. Proposed mechanism for oxidative addition of complex 1 with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$

Fig. 2. $\mathrm{S}_{\mathrm{N}} 2$ oxidative addition reaction between complex 1 and dichloromethane by interaction of LUMO of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (A) and HOMO of 1 (B) to form TS (C).

It is experimentally and computationally accepted that organic halides oxidative addition to square planar $\mathrm{Pt}(\mathrm{II})$ compounds normally occurs in $\mathrm{S}_{\mathrm{N}} 2$ fashion [22-23] including nucleophilic substitution of halide by Pt center to form a Pt-C bond, followed by subsequent coordination of halide to form an octahedral $\mathrm{Pt}(\mathrm{IV})$ product. To get more insight to the oxidation of 1 to 2 , we have computationally investigated this reaction using DFT calculations. The possible structures of the reactants, transition states, intermediates and products for the reaction of complex 1 with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ are shown in Scheme 2.

As shown in Scheme 2 and Fig. 2, the computational study proposed the formation of transition state TS including $\mathrm{Pt}-\mathrm{CH}_{2} \mathrm{Cl}-\mathrm{Cl}$ fragment. First, the Pt center of 1 attacks on carbon atom of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ to simultaneously remove the chloride ion and form $\mathrm{Pt}-\mathrm{CH}_{2} \mathrm{Cl}$ bond. TS includes the $\mathrm{Pt}-\mathrm{CH}_{2} \mathrm{Cl}-\mathrm{Cl}$ moiety with bond angle of $154.6^{\circ}$, showing a deviation from the linear arrangement. The Cl and H atoms of $\mathrm{CH}_{2} \mathrm{Cl}$ group are located in the equatorial plane of the 5coordinated carbon atom to give almost a trigonal bipyramidal geometry around the carbon of $\mathrm{CH}_{2} \mathrm{Cl}$ group. Formation of TS accompanied by the significant changes for $\mathrm{Cl}-\mathrm{CH}_{2} \mathrm{Cl}$ and $\mathrm{Pt}-\mathrm{CH}_{2} \mathrm{Cl}$ bonds. As shown in Fig. 3, $\mathrm{Cl} \cdots \mathrm{CH}_{2} \mathrm{Cl}$ distance changes from $1.795 \AA$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ to $2.373 \AA$ in TS. In contrast, the $\mathrm{Pt} \cdots \mathrm{CH}_{2} \mathrm{Cl}$ distance changes from far, at the beginning of the reaction, to $2.615 \AA$ in TS. The formation of TS followed by the formation of the ionic 5-coordinate $\left[\mathrm{Pt}\left(\mathrm{CH}_{2} \mathrm{Cl}\right) \mathrm{Me}_{2}(\mathrm{pbt})\right]^{+}$intermediate, IM. DFT calculation suggests a square pyramidal geometry for IM with the $\mathrm{CH}_{2} \mathrm{Cl}$ group in the apical position and with the chloride ion situated on the outer sphere of Pt complex. The $\mathrm{Pt}-\mathrm{CH}_{2} \mathrm{Cl}$ bond length in IM is about $2.041 \AA$, shorter than that in TS $(2.615 \AA)$, showing the completeness of bond formation between Pt center and incoming $\mathrm{CH}_{2} \mathrm{Cl}$ group. The last step includes the coordination of the free chloride ion to the Pt center of IM to form the final $\mathrm{Pt}(\mathrm{IV})$ complex 2 in which the geometry of the ligands around the Pt center is octahedral (see Fig. 3). It is clear that the bond distances of Pt (II) center with ligands in complex 1 (with $\mathrm{dsp}^{2}$ hybridization) should be shorter than those of the corresponding $\mathrm{Pt}(\mathrm{IV})$ product 2 . For example, the two $\mathrm{Pt}($ II $)-\mathrm{Me}$ bond distances in complex 1 is 2.054 and 2.046 $\AA$, while those for corresponding $\mathrm{Pt}(\mathrm{IV})-\mathrm{Me}$ ligands are 2.068 and $2.065 \AA$, in complex 2.

In an attempt to grow crystals of the new starting $\mathrm{Pt}(\mathrm{II})$ complex 1 in $\mathrm{CH}_{2} \mathrm{Cl}_{2} / n$-hexane mixture of solvents, the appropriate single crystals of the new $\mathrm{Pt}(\mathrm{IV})$ complex $\left[\mathrm{PtCl}_{2} \mathrm{Me}_{2}(\mathrm{bpt})\right]$, 3 , was obtained and determined by X-ray crystallography. The compound 3 should be resulted from chlorine atom abstraction as shown in Scheme 3. A reaction with solvent should be occurred to give 3. A similar mechanism is suggested for this process [14,24-26]. Formation of a dichloro platinum(IV) complex has also been proposed during the reaction of the $\mathrm{Pt}(\mathrm{II})$ complexes $\left[\mathrm{Pt}(\mathrm{Cl})_{2}(\mathrm{bpy})\right]$ (bpy $=2,2^{\prime}$-bipyridine) and $\left[\mathrm{PtMe}_{2}(\mathrm{dpm})\right]$ $\left(\mathrm{dpm}=\right.$ di-2-pyridylmethane) with $\mathrm{CHCl}_{3}$ [13]. The structure of complex 3 (see Fig. 4) confirms that the pbt chelating ligand is coordinated to the Pt center via the two N atoms while the S atom of benzothiazole moiety is stayed uncoordinated. The N2-Pt1-N1 angle, 75.9(4) ${ }^{\circ}$, is considerably less than the ideal value of $90^{\circ}$. The two chlorine ligands are located mutually trans to each other, with the angle $\mathrm{C} 1(2)-\mathrm{Ptl}-\mathrm{Cl}(1)=162.5(3)^{\circ}$ being significantly less than the ideal angle of $180^{\circ}$ and leaning towards the bpt chelate with for example the $\mathrm{C} 1(2)-\mathrm{Pt} 1-\mathrm{N} 2$ angle being $76.6(3)^{\circ}$. The $\mathrm{Ptl}-\mathrm{C}(13)$ distance of $2.039(17) \AA$ seems to be slightly shorter than that of the Pt1-C(14) of 2.06(2) $\AA$ and we tentatively assign this to be due to the trans influence of N ligating atom of pyridyl group being marginally greater than that of the benzothiazole moiety. This may help us in assigning the NMR data for complex 2 in which the ${ }^{2} J_{\mathrm{PHH}}$ values in the ${ }^{1} \mathrm{H}$ NMR spectrum of the complex 2 for the two methyl ligands are 72.5 Hz and 75.0 Hz , complying with the former being for the signal of the Me ligand being trans to the N ligating atom of pyridyl group.

## CONCLUSIONS

The reaction of dimethyplatinum(II) complex $\left[\mathrm{PtMe}_{2}(\mathrm{pbt})\right]$, 1, with dichloromethane, as both solvent and reagent, formed a platinum(IV) complex in which the carbon-chloride bond in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was oxidatively added to Pt center. The $\mathrm{Pt}(\mathrm{IV})$ complex 2 included two new bonds, PtCl and $\mathrm{Pt}-\mathrm{CH}_{2} \mathrm{Cl}$, which are trans to each other. The computational study suggests an $\mathrm{S}_{\mathrm{N}} 2$ mechanism which is usually accepted for oxidative addition of small organic molecules to square planar platinum complexes [22-23]. In

Pt-C(trans to $\left.\mathrm{N}_{\text {py }}\right) 2.058$
$\mathrm{Pt}-\mathrm{C}$ (trans to $\mathrm{N}_{\mathrm{b}}$ ) 2.051
Pt- $\mathrm{N}_{\mathrm{py}} 2.235$
$\mathrm{Pt}-\mathrm{N}_{\mathrm{bz}} 2.272$

Fig. 3. Energy profile for oxidative addition of 1 with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The optimized structures of the species involved in the reactions are shown. Selected bond distances $(\AA)$ are also shown. The summation of the energies of the 1 and $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was considered to be zero, and the other energy levels vary relative to this.

Scheme 3. Suggested route for formation of complex 3 from 1 in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solvent
this mechanism, the Pt center of complex 1 as a nucleophile donates electrons to the $\sigma^{*}$-orbital of the $\mathrm{Cl}_{2} \mathrm{HC}-\mathrm{Cl}$ bond by attacking the carbon atom of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ to eliminate the Cl atom of $\mathrm{Cl}_{2} \mathrm{HC}-\mathrm{Cl}$. The polar transition states obtained for these reactions contain $\mathrm{Pt}-\mathrm{CH}_{2} \mathrm{Cl}-\mathrm{Cl}$ arrangements. The cationic five-coordinate intermediate $\left[\mathrm{Pt}\left(\mathrm{CH}_{2} \mathrm{Cl}\right) \mathrm{Me}_{2}(\mathrm{pbt})\right]^{+}$, has the square pyramidal geometries. Recoordination of free
chloride to the empty site of the cationic intermediate forms the product $\left[\mathrm{PtCl}\left(\mathrm{CH}_{2} \mathrm{Cl}\right) \mathrm{Me}_{2}(\mathrm{pbt})\right]$, 2. The energy barrier for the rate determining step, i.e. formation of transition state, was calculated to be $97.5 \mathrm{~kJ} \mathrm{~mol}^{-1}$. Attempts to get a suitable crystal for $\mathrm{Pt}(\mathrm{II})$ complex 1 in the mixture of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /n-hexane, was ended up to a new dichloro platinum(IV) complex $\left[\mathrm{PtCl}_{2} \mathrm{Me}_{2}(\mathrm{bpt})\right], 3$.
